Abstract: Single crystals of L alanine admixtured cadmium sulphate were grown by slow evaporation process at room temperature. The grown compound was characterized by powder XRD analysis to confirm the crystalline nature. The cell parameters and structure of grown crystal were identified through single crystal XRD analysis. The structure of the grown crystal is monoclinic. The suitability of the crystals for optical applications was studied by UV–Vis spectroscopy which proved that the transparency of the grown crystal is 96%. Fourier transform infrared (FT-IR) spectral analysis confirmed the presence of various functional groups in the grown crystals. The mechanical property of the grown crystal was determined by Vicker’s micro hardness test and it proved the soft nature of the grown crystal.

Keywords: Crystal growth, slow evaporation, powder XRD, single crystal XRD, UV–Vis, FT-IR, Vicker’s micro hardness.

1. INTRODUCTION

Organic crystals have been extensively studied due to their non-linear optical (NLO) coefficients being often larger than those of inorganic materials. The basic structure of organic NLO materials is based on π bonding systems. Due to the overlap of π bonding electrons, delocalization of the charge distribution takes place, which leads to a high mobility of the electron density. The organic NLO materials play an important role in SHG, frequency mixing, electro-optic modulation, optical parametric oscillation, optical stability, etc. But most organic NLO crystals have usually poor mechanical and thermal properties and are susceptible to damage during processing. It is difficult to grow large optical quality crystals of these materials for device applications. Pure inorganic NLO materials typically have excellent mechanical and thermal properties but possess relatively modest optical nonlinearities because of the lack of extended π-electron delocalization [1,2]. Thus the research is focused on semi organic materials in order to obtain the advantages of both organic and inorganic materials.

Amino acid family crystals are playing an important role in the field of non-linear optical molecular crystal. Among them L-alanine (LA), with chemical formula (CH$_2$-CH-NH$_2$-COOH) is the smallest, naturally occurring chiral amino acid with a non-reactive hydrophobic methyl group (-CH$_3$) as a side chain. LA has the zwitterionic form (NH$_3^+$-C$_3$H$_7$-COO$^-$) both in crystal and in aqueous solution over a wide range of pH, which favours crystal hardness for device application. It belongs to the orthorhombic crystal system and the unit cell parameters are; a = 6.320 Å, b = 12.343 Å, c = 5.784 Å, α = β = γ = 90°. Recently, several new complexes incorporating the amino acid L-alanine have been crystallized and their structural, optical and thermal properties have also been investigated [3-5]. In the present study, L alanine admixtured cadmium sulphate [LACS] crystals were grown by slow evaporation solution growth technique. The crystals were characterized using PXRD, single crystal XRD, UV-Vis, FTIR and micro hardness studies.

2. MATERIALS AND METHODS

As per the estimated solubility data, saturated solution of cadmium sulphate (75 g/100 ml) and L alanine (16.72 g/100 ml) (99% purity) were prepared separately using doubly distilled water at room temperature using magnetic stirrer(REMI 1MLH). The prepared solutions were doubly filtered by Whatman No.1 filter paper and mixed in the ratio 3:1 and stirred well for 5 hours. The beaker containing the mixture was closed with a pin holed aluminium foil and kept at room temperature in a dust and vibration free environment for slow evaporation. Highly transparent, good quality LACS a single crystal of dimension 16x13x6 mm$^3$ were harvested on 83$^{rd}$ day and is shown in figure 1. Recrystallization was carried out repeatedly to enhance the purity of the crystal.
The expected chemical reaction is given below:

\[ CdSO_4 + CH_2CH(NH_2)COOH \rightarrow NH_2CH = (CH_3)_2COO^-CdSO_4 \]

### 3. RESULTS AND DISCUSSIONS

Various characterisation studies were carried out for the grown crystals and the results are discussed hereunder.

#### 3.1. Powder X-ray diffraction analysis

In order to confirm the structure of the grown crystal, powder X-ray diffraction was recorded at a wavelength of radiation \( \lambda = 1.540598 \) Å (Cu) using reflection scan mode. Finely crushed powder of the sample was scanned over the range of 10-80° at the scan rate of 1°/minute. The X-ray diffractogram is shown in figure 2.

The well defined sharp Bragg’s peaks at specific 20 angles in the spectra of grown crystals show high crystalline nature of the compound. PXRD pattern of the grown crystal contains some new peaks, in addition to the peaks of parent material which may be due to the presence of L alanine.

#### 3.2. Single crystal X-ray Diffraction analysis

As grown crystal had been subjected to single crystal XRD employing a Bruker AXS diffractometer using MoKα radiation (\( \lambda = 0.71073 \))Å. The single crystal XRD revealed that the crystal belonged to monoclinic system. The lattice parameter values were compared with the parent material and are shown in Table 1. The results of the present work are in good agreement with the reported values [6]. As grown crystal possessed the same crystal system as that of parent crystal but there is a tiny change in lattice constant values and cell volume.

#### 3.3. Optical transmittance spectral analysis

For optical applications, the material considered must be transparent in the entire visible region [7]. Optical transmission spectrum was recorded on PerkinElmer UV Win Lab Lambda 900 spectrophotometer in the wavelength range 200 and 800 nm as shown in figure 3.

![Figure 3. UV-Visible spectrum of LACS crystal](image-url)
The crystal showed a good transmittance in UV and in the entire visible region, suggesting the suitability of the material for NLO applications. The cut off wave length is found to be around 217 nm. The transparency of the grown crystal is 96.08%. The band gap energy of the grown crystal is 3.76 eV.

3.4. FT-IR analysis

The Fourier transform infrared spectrum of LACS was recorded in between the region 400 cm$^{-1}$ and 4000 cm$^{-1}$ and is shown in Figure 4.

![Figure 4. FTIR spectrum of LACS crystal](image)

Observed bands along with their vibrational assignments have been tabulated in Table 2.

Table 2. FTIR spectral data of LACS crystal

<table>
<thead>
<tr>
<th>Wave number in cm$^{-1}$</th>
<th>Band assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>3392</td>
<td>OH/NH$_2$ stretching</td>
</tr>
<tr>
<td>2992</td>
<td>C-H stretching in CH$_3$</td>
</tr>
<tr>
<td>1632</td>

</tr>
<tr>
<td>676</td>
<td>O-C=O in plane deformation</td>
</tr>
<tr>
<td>563</td>
<td>COO$^-$ rocking</td>
</tr>
</tbody>
</table>

The peaks at 3392 and 1632 cm$^{-1}$ correspond to NH$_2$. The frequency observed at 676 and 563 cm$^{-1}$ can be attributed to COOH vibrations. The peaks at 2992 and 852 cm$^{-1}$ confirm the presence of C-H group. The peak at 1079 cm$^{-1}$ indicates the possibility of C-N stretch and sulphate ion. O-H stretching is proved by the occurrence of the peak at 3392 cm$^{-1}$ [6-10].

3.5. Micro hardness studies

The hardness of the crystals depends on type of chemical bonding, lattice energy, Debye temperature, heat of formation and inter atomic spacing, which may differ along the crystallographic directions. Micro hardness test provides useful information about the mechanical properties like elastic constants, yield strength, resistance, pressure etc., of the materials. Vickers hardness test is the most common and reliable method for hardness measurement of solid surfaces [11]. The micro hardness of the grown crystals was measured using a Shimadzu Micro hardness Tester with a diamond indenter. In the present work, well polished crystal was mounted on a platform of the micro hardness tester and indentations were made on the grown crystals for three loads 25, 50 and 100 g and indentation time given was 10 seconds. The length of the two diagonals of diamond indenter was measured and the average was found out. For a particular load, at least two well defined indentations were considered and the average value (d) was calculated.

Vicker’s hardness number was determined using the expression

$$H_V = \frac{1.8544 \times P}{d^2}$$

where, ‘P’ is the applied load, ‘d’ is the average diagonal length of the indentation marks and the result is plotted (Figure 5). From the graph, the hardness value increased with the increasing load and hence the grown crystal exhibited the reverse indentation size effect (RISE).

![Figure 5. Variation of H$_{v}$ Vs load](image)
appeared to be due to the absence of liquid inclusions and higher stress required to form dislocations [12,13].

Yield strength is the important property for the device fabrication and it is the maximum stress that can be developed in a material without causing plastic deformation. Since n is found to be more than 2, yield strength of the material can be found out using the relation,

\[ \sigma_y = \frac{H}{3}(0.1)^{n-2} \]

The yield strength for different loads is listed in table 3. From the table, it was clear that the yield strength increased with load. Hence the grown crystal had relatively high mechanical strength.

Elastic stiffness constant \(C_{11}\) was calculated by Wooster’s empirical relation as

\[ C_{11} = \frac{H^7}{V^4} \]

Stiffness constant for different loads calculated from Vickers hardness values are given in table 3. From the table, it was clear that the stiffness constant increased with increase of load. Hence the high value of \(C_{11}\) indicated that the binding forces between the ions are quite strong [14]. The higher the hardness values, greater was the stress required to form dislocation, thus confirming greater crystalline perfection.

**4. CONCLUSION**

Good optical quality single crystals of L alanine admixtured cadmium sulphate were grown by slow evaporation solution growth method at room temperature. Powder XRD pattern confirms the crystalline nature of the grown compound. Single crystal XRD study established the crystal system of the grown crystal as monoclinic. From UV-Visible transmission spectra, it is clear that the width of the transmission window is high. This property can be used for frequency doubling and other optical applications. The presence of various functional groups stand confirmed from FT IR spectrum. Vicker’s micro hardness study revealed the softness of the grown crystals and the variation of hardness coefficient, yield strength and stiffness constant with load. Hence the grown crystals are suitable for optoelectronic applications.

**5. ACKNOWLEDGEMENT**

The authors are thankful to Indian Institute of Science, Bangalore; Bharathiar University, PSG College of Arts and Science, Coimbatore; and St. Joseph College, Trichy for extending their facilities during the course of this study.
