Abstract: This study is conducted to address the lack of route information of public transportation in Surabaya by creating an online guide that can be accessed by passengers to get complete information on maps and travel routes for public transportation. This guide is made interactive, simple, accessible, and appropriate for transport adapted to the conditions in the city of Surabaya. This research will develop an Android and iOS applications that can be used on smartphones and tablets using Android and iOS operating systems. Maps and routes are obtained from the Department of Transportation of Surabaya. A survey was done by distributing questionnaires to the passengers to determine the passengers’ need for public transportation. Maps and route are developed using OpenStreetMap, Ajax, Javascript, XML, OpenLayer, PostgreSQL, and PostGIS. The hybrid application is compiled using PhoneGap. The idea of implementing hybrid application could be seen in the diagram of Figure 1.

Key words: routes, maps, public transportation, bemo, OpenStreetMaps, android, iOS

1. INTRODUCTION

Currently one of the mass public transportation in the city of Surabaya is the type of small and medium 1000cc minibus commonly called bemo with a maximum carrying capacity of 10 persons [4]. Watkins et al [2] in the studies of open source development of mobile transit traveller OneBusAway information system for King County Metro (KCM) in Seattle suggest that the provision of good information system for public transport passengers will increase passengers’ satisfaction and increase the interest of public transport. It would be useful to encourage people to switch from the use of private transportation to the public transportation.

Furthermore, based on the observation of the initial research, there are some Android applications of TransJakarta Busway public transportation in Jakarta. Among them is Komutta that has the highest rating 4.6 out of 1,263 voters and has been downloaded more than 50,000 times in the Google Play Store.

However, all the applications that have been created can only be running on one operating system. For instance, the application that can be used on Android cannot be used in iOS. Blackberry and Windows Mobile. Conversely the one that runs on Blackberry cannot be used in other operating systems.

As a result, not all smartphone users can take advantage of software applications that have been created. This is because all of the applications initially were developed using native application and not with the hybrid application [3]. As a result, if an application is already developed as an Android native application, in order to make it available for iOS native application the developer must re-develop the application from the beginning due to different programming languages that are used to develop native applications for different operating systems. If initially the applications were developed using a hybrid technology to produce cross-platform application, for example for Android, when it would be developed for iOS, only very minor and simple changes needed to be done. The idea of implementing hybrid application could be seen in the diagram of Figure 1.

The head of IDC Operations of Indonesia, Sudev Bangah argued that many smartphones with varying price would be affordable for smartphone users who were on the middle segment market [4].

Based on the fact that market share is issued by IDC Indonesia, to increase the satisfaction of bemo passengers in Surabaya, this research will develop applications that can be used by smartphones of Android and iOS operating systems for trip planning using bemo in Surabaya using Open Street Maps. Those applications will help the passengers plan their trips based on routes, timetables, and costs.

As shown in Figure 1 the time can be shortened and costs can be saved because after developing a web-based application in the form of responsive website, it becomes a native application using PhoneGap that can then be distributed through the application store for each mobile operating system.

The applications will provide information about route guide and timetable of public transportation in Surabaya. The information will be equipped with a search feature and a trip planning using public transportation simply by typing the place of origin and destination specified by the passengers. Both the place of origin and destination can either be a street name or a landmark name and public place such as bemo stations, parks, rivers, shops, schools, and others.

The planning features will use a multimodal transport network that takes into account some factors such as multimodal...
routes, timetables, and costs to provide recommendations for the optimized route. This feature will guide the passengers to the nearest public transportation station, by giving the order of public transportation they should take, to arrive at the nearest public transportation to the destination. This feature will also be equipped with an estimation of the fare for the service.

2. HYBRID APPLICATIONS

There are several types of mobile application, which are Native App, Web App and Cross Platform Mobile App or Hybrid App. According to Stark [5], Native application is application installed on the phone, such as Android and iOS-based Smartphones. Native applications have access to the Smartphone hardware features such as camera, speaker, etc. Developers have to use different kinds of programming language to develop native applications for different platforms. To develop Android native applications, Java programming language is needed. Objective – C is used to develop iOS native applications. Native applications are available on the official application markets such as Google PlayStore for Android and iTunes App Store for iOS.

On the contrary to Native application, Web applications are not installed on the phone and they are not available on the official application markets such as Google PlayStore and iTunes App Store. However, they are easily accessed with the Smartphone’s web browsers and that means developers are only required to use HTML, CSS, and JavaScript to build Web applications. The downside for Web applications is that it cannot access certain hardware features on the smartphone [5].

Hybrid application or Cross Platform mobile application is considered to be the right solution for developer to build iOS and Android applications without mastering many programming languages and downloading any SDKs (software development kits) for each platform, but it can put the application on Google PlayStore and iTunes App Store [6]. To build a hybrid application or a cross platform mobile application both for iOS and Android, developers only need to use HTML, CSS, and JavaScript to develop a web application. Next, with PhoneGap technology, the web application will be packaged into a native application for iOS, Android and other mobile platforms [5].

A graph that highlights the differences in native, hybrid and mobile web applications can be seen in Figure 2.

3. RESEARCH METODOLOGY

3.1 Fishbone diagram

The method used in this research can be seen in Figure 3. The first step includes a survey of the timetables of public transportation, the fare of travel, and the location of public places.

Figure 3. Fishbone Diagram of Research Methodology

The first step is to compile the responsive website that has been made to be cross-platform mobile application using Phonegap. At this stage the process will begin with registration of Developer ID in the application store for each operating system, until a developer SDK for each platform is
secured. After this, the compilation of web-based applications with the SDK of each platform using phonegap, resulting in cross-platform mobile applications needs to be done. The outcomes are cross-platform mobile applications that can be used for each operating system (iOS and Android).

The second step will be the implementation and testing of applications with the following stages: Registering and uploading applications on each application store for each operating system (iOS and Android), namely AppStore for iOS and Google Play Store for Android. Testing the applications on a variety of mobile devices for each operating system with a different screen resolution size. Testing the use of applications in the real case and doing the journey planner on public transportation in Surabaya with some case studies of travel route need to be done.

The last stage or the third step will be to disseminate and evaluate the applications with the following stages: Create tutorial posters to use the application that will be shown at the terminal and all public transportation. Upload the tutorial posters at the Department of Transportation website and official Facebook page of the Department of Transportation. Finally evaluate the application by providing a place for criticisms and suggestions the make the application better.

3.2 System Design
The design of the client system is shown in the flowchart in Figure 4. Firstly, the users must choose what they want to do, whether they want to look all routes or directly get to the direction. If they choose to see all routes, all lists of bemo lines nearby their current position will be shown.

Furthermore, they have to pick one from the list to see the route on the map. However, if they want to get directly to their destination, they must choose one point of interest available in the server database. Then, they have to choose how the application detects their current location using GPS or manually clicking on the map. Nevertheless, the method to detect the user’s location still depends on whether the GPS is available on their device or not. If the application can detect the current location of the user, then it will show the routes to go to their destination using the closest line available near their current location.

4. EXPERIMENTAL RESULTS
The testing of the applications was done using two devices, namely 3.5 inch smartphone and 7 inch tablet. The first time the applications is initialized, it will display the screen like in Figure 5. There are two options to choose, namely 'Search bemo routes to destination' and 'See all existing routes of bemo'.

If the user selects the option 'See all the existing routes of bemo', then the screen shows as in Figure 6. If the user types a particular letter or word and presses 'ok' then it will display a maximum of 5 lines containing these words or letters typed by the user. If the user presses one of the available buttons from the options, then the application will bring up a page with a map of the selected line like in Figure 7.
If in Figure-5 the user selects the option 'See all the existing routes of the bemo,' the screen will display options as shown in Figure 8. If the user types a particular word (i.e. MALL) and presses 'ok' button, then it will display a maximum of 5 points of interest containing the word typed by the user. Once the user selects one of the existing points of interest, then it will be displayed like in Figure 9.

Here the user is prompted to choose whether he wants to select the starting location by GPS or to select the starting location on the map using the touchscreen. Once the initial location has been determined, it will show the route to be passed and the estimated fare to be paid as in Figure-10. In Figure-10 shows that the user originally is on Nyamplungan Street and s/he wants to travel to Ambengan Street. The first time the user is suggested to go by Line A bemo. On the way s/he should get off from the Line A bemo on Tambaksari Street and walk to Kapasari Street to get on Line B bemo. Next s/he has to get off Line B on Tambaksari Street and walk to the destination on Ambengan Street.

When the user wants to see the resulting route s/he can press on the 'view map' button, then options will appear on the display as in Figure 11 on smartphone and Figure 12 on tablet.

5. ACKNOWLEDGMENTS
This research can be conducted and accomplished by the grants from the Directorate General of Higher Education Indonesia (DIKTI) using the scheme of “Penelitian Hibah Bersaing 2015” (or 2015 Competitive Research Grant). We would like to thank The Centre of Research of Petra Christian University for their assistance to manage the grants.

6. CONCLUSIONS
Based on the experimental result, it proves that the website of this research can be used to give the information of routes, maps, varying types of bemo lines using any size of
smartphones and tablets without any difficulties. The display can always be adjusted to the screen size of the browser. In searching for the routes, there is a possibility that it does not show the nearest point because to search for the route to the POI, the reference used is the central point of the nearest route that has the bemo line to the POI. However, the result is accurate enough. This is intentionally made this way to make sure that the server does not undergo an overload at receiving many route requests. This method can be faster at least twice compared to making a calculation to all points. If the user is outside 500 meter distance, the application will search for a point of bemo location up to 1.5 kilometers from the user’s location. This happens because from the survey results the users feel that 500 meter walk is a comfortable distance to take. However, when the point cannot be located, it will be expanded into 1.5 kilometers presuming that the user can take another transportation or take a walk.
